1 Introduction

This document describes the new `phylo4` S4 classes and methods, which are intended to provide a unifying standard for the representation of phylogenetic trees and comparative data in R. The `phylobase` package was developed to help both end users and package developers by providing a common suite of tools likely to be shared by all packages designed for phylogenetic analysis, facilities for data and tree manipulation, and standardization of formats.

This standardization will benefit *end-users* by making it easier to move data and compare analyses across packages, and to keep comparative data synchronized with phylogenetic trees. Users will also benefit from a repository of functions for tree manipulation, for example tools for including or excluding subtrees (and associated phenotypic data) or improved tree and data plotting facilities. `phylobase` will benefit *developers* by freeing them to put their programming effort into developing new methods rather than into re-coding base tools. We (the `phylobase`

developers) hope `phylobase` will also facilitate code validation by providing a repository for benchmark tests, and more generally that it will help catalyze community development of comparative methods in R.

A more abstract motivation for developing `phylobase` was to improve data checking and abstraction of the tree data formats. `phylobase` can check that data and trees are associated in the proper fashion, and protects users and developers from accidentally reordering one, but not the other. It also seeks to abstract the data format so that commonly used information (for example, branch length information or the ancestor of a particular node) can be accessed without knowledge of the underlying data structure (i.e., whether the tree is stored as a matrix, or a list, or a parenthesis-based format). This is achieved through generic `phylobase` functions which which retrieve the relevant information from the data structures. The benefits of such abstraction are multiple: (1) *easier access to the relevant information* via a simple function call (this frees both users and developers from learning details of complex data structures), (2) *freedom to optimize data structures in the future without breaking code*. Having the generic functions in place to “translate” between the data structures and the rest of the program code allows program and data structure development to proceed somewhat independently. The alternative is code written for specific data structures, in which modifications to the data structure requires rewriting the entire package code (often exacting too high a price, which results in the persistence of less-optimal data structures). (3) *providing broader access to the range of tools in phylobase*. Developers of specific packages can use these new tools based on S4 objects without knowing the details of S4 programming.

The base `phylo4` class is modeled on the the `phylo` class in `ape`. `phylo4d` and `multiplylo4` extend the `phylo4` class to include data or multiple trees respectively. In addition to describing the classes and methods, this vignette gives examples of how they might be used.

2 Package overview

The `phylobase` package currently implements the following functions and data structures:

- Data structures for storing a single tree and multiple trees: `phylo4` and `multiPhylo4?`
- A data structure for storing a tree with associated tip and node data: `phylo4d`
- A data structure for storing multiple trees with one set of tip data: `multiPhylo4d`
- Functions for reading nexus files into the above data structures
- Functions for converting between the above data structures and `ape phylo` objects as well as `ade4 phylog` objects (although the latter are now deprecated ...)
- Functions for editing trees and data (i.e., subsetting and replacing)
- Functions for plotting trees and trees with data

3 Using the S4 help system

The S4 help system works similarly to the S3 help system with some small differences relating to how S4 methods are written. The `plot()` function is a good example. When we type `?plot` we are provided the help for the default plotting function which expects `x` and `y`. R also provides a way to smartly dispatch the right type of plotting function. In the case of an `ape phylo` object

(a S3 class object) R evaluates the class of the object and finds the correct functions, so the following works correctly.

```
library(ape)
set.seed(1) ## set random-number seed
rand_tree <- rcoal(10) ## Make a random tree with 10 tips
plot(rand_tree)
```

However, typing `?plot` still takes us to the default `plot` help. We have to type `?plot.phylo` to find what we are looking for. This is because S3 generics are simply functions with a dot and the class name added.

The S4 generic system is too complicated to describe here, but doesn't include the same dot notation. As a result `?plot.phylo4` doesn't work, R still finds the right plotting function.

```
library(phylobase)

##
## Attaching package: 'phylobase'
## The following object is masked from 'package:ape':
##
## edges

# convert rand_tree to a phylo4 object
rand_p4_tree <- as(rand_tree, "phylo4")
plot(rand_p4_tree)
```

All fine and good, but how to we find out about all the great features of the `phylobase` plotting function? R has two nifty ways to find it, the first is to simply put a question mark in front of the whole call:

```
`?`(plot(rand_p4_tree))
```

R looks at the class of the `rand_p4_tree` object and takes us to the correct help file (note: this only works with S4 objects). The second ways is handy if you already know the class of your object, or want to compare to generics for different classes:

```
`?`(method, plot("phylo4"))
```

More information about how S4 documentation works can be found in the `methods` package, by running the following command.

```
help('Documentation', package="methods")
```

4 Trees without data

You can start with a tree — an object of class `phylo` from the `ape` package (e.g., read in using the `read.tree()` or `read.nexus()` functions), and convert it to a `phylo4` object.

For example, load the raw *Geospiza* data:

```

library(phylobase)
data(geospiza_raw)
## what does it contain?
names(geospiza_raw)

## [1] "tree" "data"

```

Convert the S3 tree to a S4 phylo4 object using the as() function:

```

(g1 <- as(geospiza_raw$tree, "phylo4"))

##      label node ancestor edge.length node.type
## 1  fuliginosa   1     24    0.05500     tip
## 2   fortis     2     24    0.05500     tip
## 3 magnirostris  3     23    0.11000     tip
## 4 conirostris  4     22    0.18333     tip
## 5   scandens  5     21    0.19250     tip
## 6  difficilis  6     20    0.22800     tip
## 7   pallida   7     25    0.08667     tip
## 8   parvulus  8     27    0.02000     tip
## 9  psittacula  9     27    0.02000     tip
## 10  pauper    10    26    0.03500     tip
## 11 Platyspiza 11    18    0.46550     tip
## 12   fusca   12    17    0.53409     tip
## 13 Pinaroloxias 13    16    0.58333     tip
## 14  olivacea  14    15    0.88077     tip
## 15      <NA>  15     0         NA      root
## 16      <NA>  16    15    0.29744 internal
## 17      <NA>  17    16    0.04924 internal
## 18      <NA>  18    17    0.06859 internal
## 19      <NA>  19    18    0.13404 internal
## 20      <NA>  20    19    0.10346 internal
## 21      <NA>  21    20    0.03550 internal
## 22      <NA>  22    21    0.00917 internal
## 23      <NA>  23    22    0.07333 internal
## 24      <NA>  24    23    0.05500 internal
## 25      <NA>  25    19    0.24479 internal
## 26      <NA>  26    25    0.05167 internal
## 27      <NA>  27    26    0.01500 internal

```

The (internal) nodes appear with labels <NA> because they are not defined:

```

nodeLabels(g1)

## 15 16 17 18 19 20 21 22 23 24 25 26 27
## NA NA NA NA NA NA NA NA NA NA NA NA NA

```

You can also retrieve the node labels with labels(g1,"internal").
A simple way to assign the node numbers as labels (useful for various checks) is

```
nodeLabels(g1) <- paste("N", nodeId(g1, "internal"), sep="")
head(g1, 5)
```

```
##           label node ancestor edge.length node.type
## 1 fuliginosa   1      24      0.05500      tip
## 2 fortis       2      24      0.05500      tip
## 3 magnirostris 3      23      0.11000      tip
## 4 conirostris  4      22      0.18333      tip
## 5 scandens    5      21      0.19250      tip
```

The `summary` method gives a little extra information, including information on the distribution of branch lengths:

```
summary(g1)
```

```
##
## Phylogenetic tree : g1
##
## Number of tips      : 14
## Number of nodes    : 13
## Branch lengths:
##   mean              : 0.1764008
##   variance          : 0.04624379
##   distribution :
##   Min. 1st Qu. Median Mean 3rd Qu. Max.
## 0.00917 0.04985 0.08000 0.17640 0.21912 0.88077
```

Print tip labels:

```
tipLabels(g1)
```

```
##           1           2           3           4           5
## "fuliginosa" "fortis" "magnirostris" "conirostris" "scandens"
##           6           7           8           9          10
## "difficilis" "pallida" "parvulus" "psittacula" "pauper"
##           11          12          13          14
## "Platyspiza" "fusca" "Pinaroloxias" "olivacea"
```

(`labels(g1,"tip")` would also work.)

You can modify labels and other aspects of the tree — for example, to convert all the labels to lower case:

```
tipLabels(g1) <- tolower(tipLabels(g1))
```

You could also modify selected labels, e.g. to modify the labels in positions 11 and 13 (which happen to be the only labels with uppercase letters):

```
tipLabels(g1)[c(11, 13)] <- c("platypiza", "pinaroloxias")
```

Note that for a given tree, `phylobase` always return the `tipLabels` in the same order.
Print node numbers (in edge matrix order):

```
nodeId(g1, type='all')
```

```
## [1] 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23  
## [24] 24 25 26 27
```

Does it have information on branch lengths?

```
hasEdgeLength(g1)
```

```
## [1] TRUE
```

It does! What do they look like?

```
edgeLength(g1)
```

```
## 15-16 16-17 17-18 18-19 19-20 20-21 21-22 22-23 23-24  
## 0.29744 0.04924 0.06859 0.13404 0.10346 0.03550 0.00917 0.07333 0.05500  
## 24-1 24-2 23-3 22-4 21-5 0-15 20-6 19-25 25-7  
## 0.05500 0.05500 0.11000 0.18333 0.19250 NA 0.22800 0.24479 0.08667  
## 25-26 26-27 27-8 27-9 26-10 18-11 17-12 16-13 15-14  
## 0.05167 0.01500 0.02000 0.02000 0.03500 0.46550 0.53409 0.58333 0.88077
```

Note that the root has `<NA>` as its length.

Print edge labels (also empty in this case — therefore all `NA`):

```
edgeLabels(g1)
```

```
## 15-16 16-17 17-18 18-19 19-20 20-21 21-22 22-23 23-24 24-1 24-2 23-3  
## NA NA NA NA NA NA NA NA NA NA NA NA  
## 22-4 21-5 0-15 20-6 19-25 25-7 25-26 26-27 27-8 27-9 26-10 18-11  
## NA NA NA NA NA NA NA NA NA NA NA NA  
## 17-12 16-13 15-14  
## NA NA NA
```

You can also use this function to label specific edges:

```
edgeLabels(g1)["23-24"] <- "an edge"
```

```
edgeLabels(g1)
```

```
## 15-16 16-17 17-18 18-19 19-20 20-21 21-22  
## NA NA NA NA NA NA NA  
## 22-23 23-24 24-1 24-2 23-3 22-4 21-5  
## NA "an edge" NA NA NA NA NA  
## 0-15 20-6 19-25 25-7 25-26 26-27 27-8  
## NA NA NA NA NA NA NA  
## 27-9 26-10 18-11 17-12 16-13 15-14  
## NA NA NA NA NA NA
```

The edge labels are named according to the nodes they connect (ancestor-descendant). You can get the edge(s) associated with a particular node:

```
getEdge(g1, 24) # default uses descendant node
##      24
## "23-24"

getEdge(g1, 24, type="ancestor") # edges using ancestor node
##      24      24
## "24-1" "24-2"
```

These results can in turn be passed to the function `edgeLength` to retrieve the length of a given set of edges:

```
edgeLength(g1)[getEdge(g1, 24)]
## 23-24
## 0.055

edgeLength(g1)[getEdge(g1, 24, "ancestor")]
## 24-1 24-2
## 0.055 0.055
```

Is it rooted?

```
isRooted(g1)
## [1] TRUE
```

Which node is the root?

```
rootNode(g1)
## N15
## 15
```

Does it contain any polytomies?

```
hasPoly(g1)
## [1] FALSE
```

Is the tree ultrametric?

```
isUltrametric(g1)
## [1] TRUE
```

You can also get the depth (distance from the root) of any given node or the tips:

```
nodeDepth(g1, 23)

## Warning: 'nodeDepth' is deprecated.
## Use 'nodeHeight' instead.
## See help("Deprecated")

##      N23
## 0.77077

depthTips(g1)

## Warning: 'depthTips' is deprecated.
## Use 'nodeHeight' instead.
## See help("Deprecated")
## Warning: 'nodeDepth' is deprecated.
## Use 'nodeHeight' instead.
## See help("Deprecated")

##   fuliginosa      fortis magnirostris conirostris      scandens
##   0.88077      0.88077      0.88077      0.88077      0.88077
##   difficilis      pallida      parvulus      psittacula      pauper
##   0.88077      0.88077      0.88077      0.88077      0.88077
##   platyspiza      fusca pinaroloxias      olivacea
##   0.88077      0.88077      0.88077      0.88077
```

5 Trees with data

The `phylo4d` class matches trees with data, or combines them with a data frame to make a `phylo4d` (tree-with-data) object.

Now we'll take the *Geospiza* data from `geospiza_raw$data` and merge it with the tree. First, let's prepare the data:

```
g1 <- as(geospiza_raw$tree, "phylo4d")
geodata <- geospiza_raw$data
```

However, since *G. olivacea* is included in the tree but not in the data set, we will initially run into some trouble:

```
g2 <- phylo4d(g1, geodata)

## Error in formatData(phy = x, dt = tip.data, type = "tip", ...): The following
## nodes are not found in the dataset: olivacea
```

To deal with *G. olivacea* missing from the data, we have a few choices. The easiest is to use `missing.data="warn"` to allow R to create the new object with a warning (you can also use `missing.data="OK"` to proceed without warnings):

```
g2 <- phylo4d(g1, geodata, missing.data="warn")
```

```
## Warning in formatData(phy = x, dt = tip.data, type = "tip", ...): The following
nodes are not found in the dataset:  olivacea
```

Another way to deal with this would be to use `prune()` to drop the offending tip from the tree first:

```
g1sub <- prune(g1, "olivacea")
g1B <- phylo4d(g1sub, geodata)
```

The difference between the two objects is that the species *G. olivacea* is still present in the tree but has no data (i.e., NA) associated with it. In the other case, *G. olivacea* is not included in the tree anymore. The approach you choose depends on the goal of your analysis.

You can summarize the new object with the function `summary`. It breaks down the statistics about the traits based on whether it is associated with the tips for the internal nodes:

```
summary(g2)
```

```
##
## Phylogenetic tree : as(x, "phylo4")
##

```

Or use `tdata()` to extract the data (i.e., `tdata(g2)`). By default, `tdata()` will retrieve tip data, but you can also get internal node data only (`tdata(tree, "internal")`) or — if the tip and node data have the same format — all the data combined (`tdata(tree, "allnode")`).

If you want to plot the data (e.g. for checking the input), `plot(tdata(g2))` will create the default plot for the data — in this case, since it is a data frame [**this may change in future versions but should remain transparent**] this will be a pairs plot of the data.

6 Subsetting

The `subset` command offers a variety of ways of extracting portions of a `phylo4` or `phylo4d` tree, keeping any tip/node data consistent.

tips.include give a vector of tips (names or numbers) to retain

tips.exclude give a vector of tips (names or numbers) to drop

mrca give a vector of node or tip names or numbers; extract the clade containing these taxa

node.subtree give a node (name or number); extract the subtree starting from this node

Different ways to extract the *fuliginosa-scandens* clade:

```
subset(g2, tips.include=c("fuliginosa", "fortis", "magnirostris",
                          "conirostris", "scandens"))
subset(g2, node.subtree=21)
subset(g2, mrca=c("scandens", "fortis"))
```

One could drop the clade by doing

```
subset(g2, tips.exclude=c("fuliginosa", "fortis", "magnirostris",
                          "conirostris", "scandens"))
subset(g2, tips.exclude=names(descendants(g2, MRCA(g2, c("difficilis",
                                                       "fortis")))))
```

7 Tree-walking

phylobase provides many functions that allows users to explore relationships between nodes on a tree (tree-walking and tree traversal). Most functions work by specifying the `phylo4` (or `phylo4d`) object as the first argument, the node numbers/labels as the second argument (followed by some additional arguments).

`getNode` allows you to find a node based on its node number or its label. It returns a vector with node numbers as values and labels as names:

```
data(geospiza)
getNode(geospiza, 10)

## pauper
##      10

getNode(geospiza, "pauper")

## pauper
##      10
```

If no node is specified, they are all returned, and if a node can't be found it's returned as a `NA`. It is possible to control what happens when a node can't be found:

```
getNode(geospiza)

##   fuliginosa      fortis magnirostris conirostris      scandens
##         1         2         3         4         5
##   difficilis    pallida      parvulus    psittacula      pauper
##         6         7         8         9         10
##   Platyspiza      fusca Pinaroloxias      olivacea      N15
##        11        12        13        14        15
##        N16        N17        N18        N19        N20
##        16        17        18        19        20
##        N21        N22        N23        N24        N25
##        21        22        23        24        25
##        N26        N27
##        26        27

getNode(geospiza, 10:14)

##      pauper Platyspiza      fusca Pinaroloxias      olivacea
##         10         11         12         13         14

getNode(geospiza, "melanogaster", missing="OK") # no warning

## <NA>
##   NA

getNode(geospiza, "melanogaster", missing="warn") # warning!

## Warning in getNode(geospiza, "melanogaster", missing = "warn"): Some nodes not
## found among all nodes in tree: melanogaster
```

```
## <NA>
## NA
```

children and ancestor give the immediate neighboring nodes:

```
children(geospiza, 16)
##          N17 Pinaroloxias
##          17          13

ancestor(geospiza, 16)
## N15
## 15
```

while descendants and ancestors can traverse the tree up to the tips or root respectively:

```
descendants(geospiza, 16) # by default returns only the tips

## Pinaroloxias      fusca  Platyspiza  difficilis  scandens
##          13          12          11          6          5
## conirostris magnirostris  fuliginosa      fortis      pallida
##          4          3          1          2          7
##      pauper      parvulus  psittacula
##          10          8          9

descendants(geospiza, "all") # also include the internal nodes

## Warning in getNode(phy, node, missing = "warn"): Some nodes not found among
all nodes in tree: all

## named list()

ancestors(geospiza, 20)
## N19 N18 N17 N16 N15
## 19 18 17 16 15

ancestors(geospiza, 20, "ALL") # uppercase ALL includes self

## N20 N19 N18 N17 N16 N15
## 20 19 18 17 16 15
```

siblings returns the other node(s) associated with the same ancestor:

```
siblings(geospiza, 20)
## N25
## 25

siblings(geospiza, 20, include.self=TRUE)
```

```
## N20 N25
## 20 25
```

MRCA returns the most common recent ancestor for a set of tips, and shortest path returns the nodes connecting 2 nodes:

```
MRCA(geospiza, 1:6)

## N20
## 20

shortestPath(geospiza, 4, "pauper")

## N19 N20 N21 N22 N25 N26
## 19 20 21 22 25 26
```

8 multiPhylo4 classes

multiPhylo4 classes are not yet implemented but will be coming soon.

9 Examples

9.1 Constructing a Brownian motion trait simulator

This section will describe a way of constructing a simulator that generates trait values for extant species (tips) given a tree with branch lengths, assuming a model of Brownian motion.

We can use `as(tree, "phylo4vcov")` to coerce the tree into a variance-covariance matrix form, and then use `mvrnorm` from the `MASS` package to generate a set of multivariate normally distributed values for the tips. (A benefit of this approach is that we can very quickly generate a very large number of replicates.) This example illustrates a common feature of working with `phylobase` — combining tools from several different packages to operate on phylogenetic trees with data.

We start with a randomly generated tree using `rcoal()` from `ape` to generate the tree topology and branch lengths:

```
set.seed(1001)
tree <- as(rcoal(12), "phylo4")
```

Next we generate the phylogenetic variance-covariance matrix (by coercing the tree to a `phylo4vcov` object) and pick a single set of normally distributed traits (using `MASS:mvrnorm` to pick a multivariate normal deviate with a variance-covariance matrix that matches the structure of the tree).

```
vmat <- as(tree, "phylo4vcov")
vmat <- cov2cor(vmat)
library(MASS)
trvec <- mvrnorm(1, mu=rep(0, 12), Sigma=vmat)
```

The last step (easy) is to convert the `phylo4vcov` object back to a `phylo4d` object:

```
treed <- phylo4d(tree, tip.data=as.data.frame(trvec))
plot(treed)
```

A Definitions/slots

This section details the internal structure of the `phylo4`, `multiphylo4` (coming soon!), `phylo4d`, and `multiphylo4d` (coming soon!) classes. The basic building blocks of these classes are the `phylo4` object and a dataframe. The `phylo4` tree format is largely similar to the one used by `phylo` class in the package `ape`¹.

We use “edge” for ancestor-descendant relationships in the phylogeny (sometimes called “branches”) and “edge lengths” for their lengths (“branch lengths”). Most generally, “nodes” are all species in the tree; species with descendants are “internal nodes” (we often refer to these just as “nodes”, meaning clear from context); “tips” are species with no descendants. The “root node” is the node with no ancestor (if one exists).

A.1 `phylo4`

Like `phylo`, the main components of the `phylo4` class are:

edge a 2-column matrix of integers, with N rows for a rooted tree or $N - 1$ rows for an unrooted tree and column names `ancestor` and `descendant`. Each row contains information on one edge in the tree. See below for further constraints on the edge matrix.

edge.length numeric list of edge lengths (length N (rooted) or $N - 1$ (unrooted) or empty (length 0))

tip.label character vector of tip labels (required), with length=# of tips. Tip labels need not be unique, but data-tree matching with non-unique labels will cause an error

node.label character vector of node labels, length=# of internal nodes or 0 (if empty). Node labels need not be unique, but data-tree matching with non-unique labels will cause an error

order character: “preorder”, “postorder”, or “unknown” (default), describing the order of rows in the edge matrix. , “pruningwise” and “cladewise” are accepted for compatibility with `ape`

The edge matrix must not contain NAs, with the exception of the root node, which has an NA for `ancestor`. `phylobase` does not enforce an order on the rows of the edge matrix, but it stores information on the current ordering in the `@order` slot — current allowable values are “unknown” (the default), “preorder” (equivalent to “cladewise” in `ape`) or “postorder”².

The basic criteria for the edge matrix are similar to those of `ape`, as documented it’s tree specification³. This is a modified version of those rules, for a tree with n tips and m internal nodes:

¹<http://ape.mpl.ird.fr/>

²see http://en.wikipedia.org/wiki/Tree_traversal for more information on orderings. (`ape`’s “pruningwise” is “bottom-up” ordering).

³ape.mpl.ird.fr/misc/FormatTreeR_28July2008.pdf

- Tips (no descendants) are coded $1, \dots, n$, and internal nodes (≥ 1 descendant) are coded $n + 1, \dots, n + m$ ($n + 1$ is the root). Both series are numbered with no gaps.
- The first (ancestor) column has only values $> n$ (internal nodes): thus, values $\leq n$ (tips) appear only in the second (descendant) column)
- all internal nodes [not including the root] must appear in the first (ancestor) column at least once [unlike `ape`, which nominally requires each internal node to have at least two descendants (although it doesn't absolutely prohibit them and has a `collapse.singles` function to get rid of them), `phylobase` does allow these "singleton nodes" and has a method `hasSingle` for detecting them]. Singleton nodes can be useful as a way of representing changes along a lineage; they are used this way in the `ouch` package.
- the number of occurrences of a node in the first column is related to the nature of the node: once if it is a singleton, twice if it is dichotomous (i.e., of degree 3 [counting ancestor as well as descendants]), three times if it is trichotomous (degree 4), and so on.

`phylobase` does not technically prohibit reticulations (nodes or tips that appear more than once in the descendant column), but they will probably break most of the methods. Disconnected trees, cycles, and other exotica are not tested for, but will certainly break the methods.

We have defined basic methods for `phylo4:show`, `print`, and a variety of accessor functions (see help files). `summary` does not seem to be terribly useful in the context of a "raw" tree, because there is not much to compute.

A.2 phylo4d

The `phylo4d` class extends `phylo4` with data. Tip data, and (internal) node data are stored separately, but can be retrieved together or separately with `tdata(x, "tip")`, `tdata(x, "internal")` or `tdata(x, "all")`. There is no separate slot for edge data, but these can be stored as node data associated with the descendant node.
