

# Package ‘marmap’

November 19, 2020

**Type** Package

**Title** Import, Plot and Analyze Bathymetric and Topographic Data

**Version** 1.0.5

**Date** 2020-11-19

**Author** Eric Pante, Benoit Simon-Bouhet, and Jean-Olivier Irisson

**Maintainer** Benoit Simon-Bouhet <besibo@gmail.com>

**Depends** R (>= 2.10)

**Imports** DBI, RSQLite, gdistance, geosphere, sp, raster, ncd4,  
plotrix, shape, reshape2, adehabitatMA, ggplot2, methods

**Suggests** maps, mapdata, lattice, mapproj, R.rsp

**BugReports** <https://github.com/ericpante/marmap/issues>

**Description** Import xyz data from the NOAA (National Oceanic and Atmospheric Administration, <<https://www.noaa.gov>>), GEBCO (General Bathymetric Chart of the Oceans, <<https://www.gebco.net>>) and other sources, plot xyz data to prepare publication-ready figures, analyze xyz data to extract transects, get depth / altitude based on geographical coordinates, or calculate z-constrained least-cost paths.

**License** GPL (>= 3)

**URL** <https://github.com/ericpante/marmap>

**VignetteBuilder** R.rsp

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2020-11-19 14:50:03 UTC

---

`aleutians`*Bathymetric data for the Aleutians (Alaska)*

---

## Description

Bathymetric matrix of class `bathy` created from NOAA GEODAS data.

## Usage

```
data(aleutians)
```

## Details

Data imported from the NOAA GEODAS Grid Translator webpage (<https://maps.ngdc.noaa.gov/viewers/wcs-client/>) and transformed into an object of class `bathy` by `as.bathy`.

## Value

A text file.

## Author(s)

see <https://maps.ngdc.noaa.gov/viewers/wcs-client/>

## See Also

[as.bathy](#), [read.bathy](#), [antimeridian.box](#)

## Examples

```
# load celt data
data(aleutians)

# class "bathy"
class(aleutians)
summary(aleutians)

# test plot.bathy
plot(aleutians, image = TRUE,
     bpal = list(c(0, max(aleutians), "grey"),
                c(min(aleutians), 0, "darkblue", "lightblue")),
     land = TRUE, lwd = 0.1, axes = FALSE)
antimeridian.box(aleutians, 10)
```

---

antimeridian.box	<i>Adds a box to maps including antimeridian</i>
------------------	--

---

### Description

Adds a box on maps including the antimeridian (180)

### Usage

```
antimeridian.box(object, tick.spacing)
```

### Arguments

object	matrix of class bathy
tick.spacing	spacing between tick marks (in degrees, default=20)

### Value

The function adds a box and tick marks to an existing plot which contains the antimeridian line (180 degrees).

### Author(s)

Eric Pante & Benoit Simon-Bouhet

### See Also

[plot.bathy](#)

### Examples

```
data(aleutians)

# default plot:
plot(aleutians,n=1)

# plot with corrected box and labels:
plot(aleutians,n=1,axes=FALSE)
antimeridian.box(aleutians, 10)
```

---

as.bathy                      *Convert to bathymetric data in an object of class bathy*

---

**Description**

Reads either an object of class `RasterLayer`, `SpatialGridDataFrame` or a three-column `data.frame` containing longitude (x), latitude (y) and depth (z) data and converts it to a matrix of class `bathy`.

**Usage**

```
as.bathy(x)
```

**Arguments**

x                      Object of `RasterLayer` or `SpatialGridDataFrame`, or a three-column `data.frame` with longitude (x), latitude (y) and depth (z) (no default)

**Details**

x can contain data downloaded from the NOAA GEODAS Grid Translator webpage (<http://www.ngdc.noaa.gov/mgg/gdas/gd>) in the form of an xyz table. The function `as.bathy` can also be used to transform objects of class `raster` (see package `raster`) and `SpatialGridDataFrame` (see package `sp`).

**Value**

The output of `as.bathy` is a matrix of class `bathy`, which dimensions and resolution are identical to the original object. The class `bathy` has its own methods for summarizing and plotting the data.

**Author(s)**

Benoit Simon-Bouhet

**See Also**

[summary.bathy](#), [plot.bathy](#), [read.bathy](#), [as.xyz](#), [as.raster](#), [as.SpatialGridDataFrame](#).

**Examples**

```
# load NW Atlantic data
data(nw.atlantic)

# use as.bathy
atl <- as.bathy(nw.atlantic)

# class "bathy"
class(atl)

# summarize data of class "bathy"
summary(atl)
```

---

`as.raster`*Convert bathymetric data to a raster layer*

---

**Description**

Transforms an object of class `bathy` to a raster layer.

**Usage**

```
as.raster(bathy)
```

**Arguments**

`bathy` an object of class `bathy`

**Details**

`as.raster` transforms `bathy` objects into objects of class `RasterLayer` as defined in the `raster` package. All methods from the `raster` package are thus available for bathymetric data (e.g. rotations, projections...).

**Value**

An object of class `RasterLayer` with the same characteristics as the `bathy` object (same longitudinal and latitudinal ranges, same resolution).

**Author(s)**

Benoit Simon-Bouhet

**See Also**

[as.xyz](#), [as.bathy](#), [as.SpatialGridDataFrame](#)

**Examples**

```
# load Hawaii bathymetric data
data(hawaii)

# use as.raster
r.hawaii <- as.raster(hawaii)

# class "RasterLayer"
class(r.hawaii)

# Summaries
summary(hawaii)
summary(r.hawaii)
```

```
# structure of the RasterLayer object
str(r.hawaii)

## Not run:
# Plots
#require(raster)
plot(hawaii, image=TRUE, lwd=.2)
plot(r.hawaii)

## End(Not run)
```

---

as.SpatialGridDataFrame

*Convert bathymetric data to a spatial grid*

---

### Description

Transforms an object of class bathy to a SpatialGridDataFrame object.

### Usage

```
as.SpatialGridDataFrame(bathy)
```

### Arguments

bathy            an object of class bathy

### Details

as.SpatialGridDataFrame transforms bathy objects into objects of class SpatialGridDataFrame as defined in the sp package. All methods from the sp package are thus available for bathymetric data (e.g. rotations, projections...).

### Value

An object of class SpatialGridDataFrame with the same characteristics as the bathy object (same longitudinal and latitudinal ranges, same resolution).

### Author(s)

Benoit Simon-Bouhet

### See Also

[as.xyz](#), [as.bathy](#), [as.raster](#)

## Examples

```
# load Hawaii bathymetric data
data(hawaii)

# use as.SpatialGridDataFrame
sp.hawaii <- as.SpatialGridDataFrame(hawaii)

# Summaries
summary(hawaii)
summary(sp.hawaii)

# structure of the SpatialGridDataFrame object
str(sp.hawaii)

# Plots
plot(hawaii, image=TRUE, lwd=.2)
image(sp.hawaii)
```

---

as.xyz

*Convert to xyz format*

---

## Description

Converts a matrix of class bathy into a three-column data.frame containing longitude, latitude and depth data.

## Usage

```
as.xyz(bathy)
```

## Arguments

bathy            matrix of class bathy.

## Details

The use of `as.bathy` and `as.xyz` allows to swith back and forth between the long format (xyz) and the wide format of class bathy suitable for plotting bathymetric maps, computing least cost distances, etc. `as.xyz` is especially usefull for exporting xyz files when data are obtained using `subsetSQL`, i.e. bathymetric matrices of class bathy.

## Value

Three-column data.frame with a format similar to xyz files downloaded from the NOAA GEODAS Grid Translator webpage (<https://maps.ngdc.noaa.gov/viewers/wcs-client/>). The first column contains longitude data, the second contains latitude data and the third contains depth/elevation data.

**Author(s)**

Benoit Simon-Bouhet

**See Also**[as.bathy](#), [summary.bathy](#)**Examples**

```
# load celt data
data(celt)
dim(celt)
class(celt)
summary(celt)
plot(celt, deep= -300, shallow= -25, step=25)

# use as.xyz
celt2 <- as.xyz(celt)
dim(celt2)
class(celt2)
summary(celt2)
```

autoplot.bathy

*Ploting bathymetric data with ggplot***Description**

Plots contour or image map from bathymetric data matrix of class bathy with ggplot2

**Usage**

```
## S3 method for class 'bathy'
autoplot(x, geom="contour", mapping=NULL, coast=TRUE, ...)
```

**Arguments**

x	bathymetric data matrix of class bathy, imported using <a href="#">read.bathy</a>
geom	geometry to use for the plot, i.e. type of plot; can be 'contour', 'tile' or 'raster'. contour does a contour plot. tile and raster produce an image plot. tile allows true geographical projection through <a href="#">coord_map</a> . raster only allows approximate projection but is faster to plot. Names can be abbreviated. Geometries can be combined by specifying several in a vector.
mapping	additional mappings between the data obtained from calling <a href="#">fortify.bathy</a> on x and the aesthetics for all geoms. When not NULL, this is a call to aes().
coast	boolean; wether to highlight the coast (isobath 0 m) as a black line
...	passed to the chosen geom(s)

**Details**

`fortify.bathy` is called with argument `x` to produce a data.frame compatible with `ggplot2`. Then layers are added to the plot based on the argument `geom`. Finally, the whole plot is projected geographically using `coord_map` (for `geom="contour"`) or an approximation thereof.

**Author(s)**

Jean-Olivier Irisson

**See Also**

[fortify.bathy](#), [plot.bathy](#), [read.bathy](#), [summary.bathy](#)

**Examples**

```
# load NW Atlantic data and convert to class bathy
data(nw.atlantic)
at1 <- as.bathy(nw.atlantic)

# basic plot
## Not run:
  library("ggplot2")
autoplot(at1)

# plot images
autoplot(at1, geom=c("tile"))
autoplot(at1, geom=c("raster")) # faster but not resolution independant

# plot both!
autoplot(at1, geom=c("raster", "contour"))

# geom names can be abbreviated
autoplot(at1, geom=c("r", "c"))

# do not highlight the coastline
autoplot(at1, coast=FALSE)

# better colour scale
autoplot(at1, geom=c("r", "c")) +
  scale_fill_gradient2(low="dodgerblue4", mid="gainsboro", high="darkgreen")

# set aesthetics
autoplot(at1, geom=c("r", "c"), colour="white", size=0.1)

# topographical colour scale, see ?scale_fill_etopo
autoplot(at1, geom=c("r", "c"), colour="white", size=0.1) + scale_fill_etopo()

# add sampling locations
data(metallo)
last_plot() + geom_point(aes(x=lon, y=lat), data=metal, alpha=0.5)

# an alternative contour map making use of additional mappings
```

```
# see ?stat_contour in ggplot2 to understand the ..level.. argument
autoplot(atl, geom="contour", mapping=aes(colour=..level..))

## End(Not run)
```

---

celt

*Bathymetric data for the North Est Atlantic*

---

## Description

Bathymetric matrix of class bathy created from NOAA GEODAS data.

## Usage

```
data(celt)
```

## Details

Data imported from the NOAA GEODAS Grid Translator webpage (<https://maps.ngdc.noaa.gov/viewers/wcs-client/>) and transformed into an object of class bathy by `as.bathy`.

## Value

A text file.

## Author(s)

see <https://maps.ngdc.noaa.gov/viewers/wcs-client/>

## See Also

[as.bathy](#), [read.bathy](#)

## Examples

```
# load celt data
data(celt)

# class "bathy"
class(celt)
summary(celt)

# test plot.bathy
plot(celt, deep=-300, shallow=-50, step=25)
```

---

`check.bathy`*Sort bathymetric data matrix by increasing latitude and longitude*

---

**Description**

Reads a bathymetric data matrix and orders its rows and columns by increasing latitude and longitude.

**Usage**

```
check.bathy(x)
```

**Arguments**

`x` a matrix

**Details**

`check.bathy` allows to sort rows and columns by increasing latitude and longitude, which is necessary for plotting with the function `image` (package `graphics`). `check.bathy` is used within the `marmap` functions `read.bathy` and `as.bathy` (it is also used in `getNOAA.bathy` through `as.bathy`).

**Value**

The output of `check.bathy` is an ordered matrix.

**Author(s)**

Eric Pante

**See Also**

[read.bathy](#), [as.bathy](#), [getNOAA.bathy](#)

**Examples**

```
matrix(1:100, ncol=5, dimnames=list(20:1, c(3,2,4,1,5))) -> a
check.bathy(a)
```

---

col2alpha	<i>Adds alpha transparency to a (vector of) color(s)</i>
-----------	--

---

### Description

Adds transparency to a color or a vector of colors by specifying one or several alpha values.

### Usage

```
col2alpha(color, alpha = 0.5)
```

### Arguments

color	a (vector of) color codes or names
alpha	a value (or vector of values) between 0 (full transparency) and 1 (no transparency).

### Details

When the size of color and alpha vectors are different, alpha values are recycled.

### Value

A (vector) of color code(s).

### Author(s)

Benoit Simon-Bouhet

### Examples

```
# Generate random data
dat <- rnorm(4000)

# plot with plain color for points
plot(dat, pch=19, col="red")

# Add some transparency to get a better idea of density
plot(dat, pch=19, col=col2alpha("red", .3))

# Same color for all points but with increasing alpha (decreasing transparency)
plot(dat, pch=19, col=col2alpha(rep("red", 4000), seq(0, 1, len=4000)))

# Two colors, same alpha
plot(dat, pch=19, col=col2alpha(rep(c("red", "purple"), each=2000), .2))

# Four colors, gradient of transparency for each color
plot(dat, pch=19, col=col2alpha(rep(c("blue", "purple", "red", "orange"), each=1000), seq(.1, .6, len=1000)))
```

```
# Alpha transparency applied to a gradient of colors
plot(dat,pch=19,col=col2alpha(rainbow(4000),.5))
```

---

collate.bathy	<i>Collates two bathy matrices with data from either sides of the antimeridian</i>
---------------	--

---

### Description

Collates two bathy matrices, one with longitude 0 to 180 degrees East, and the other with longitude 0 to 180 degrees West

### Usage

```
collate.bathy(east,west)
```

### Arguments

east	matrix of class bathy with eastern data (West of antimeridian)
west	matrix of class bathy with western data (East of antimeridian)

### Details

This function is meant to be used with `read.bathy()` or `readGEBCO.bathy()`, when data is downloaded from either sides of the antimeridian line (180 degrees longitude). If, for example, data is downloaded from GEBCO for longitudes of 170E-180 and 180-170W, `collate.bathy()` will create a single matrix of class bathy with a coordinate system going from 170 to 190 degrees longitude.

`getNOAA.bathy()` deals with data from both sides of the antimeridian and does not need further processing with `collate.bathy()`.

### Value

A single matrix of class bathy that can be interpreted by `plot.bathy`. When plotting collated data (with longitudes 0 to 180 and 180 to 360 degrees), plots can be modified to display the conventional coordinate system (with longitudes 0 to 180 and -180 to 0 degrees) using function `antimeridian.box()`.

### Author(s)

Eric Pante

### See Also

[getNOAA.bathy](#), [summary.bathy](#), [plot.bathy](#), [antimeridian.box](#)

**Examples**

```
## faking two datasets using aleutians, for this example
## "a" and "b" simulate two datasets downloaded from GEBCO, for ex.
data(aleutians)
aleutians[1:181,] -> a ; "bathy" -> class(a)
aleutians[182:601,] -> b ; "bathy" -> class(b)
-(360-as.numeric(rownames(b))) -> rownames(b)

## check these objects with summary(): pay attention of the Longitudinal range
summary(aleutians)
summary(a)
summary(b)

## merge datasets:
collate.bathy(a,b) -> collated
summary(collated) # should be identical to summary(aleutians)
```

---

combine.buffers	<i>Create a new, (non circular) composite buffer from a list of existing buffers.</i>
-----------------	---

---

**Description**

Creates a new bathy object from a list of existing buffers of compatible dimensions.

**Usage**

```
combine.buffers(...)
```

**Arguments**

...                    2 or more buffer objects as produced by [create.buffer](#). All bathy objects within the buffer objects must be compatible: they should have the same dimensions (same number of rows and columns) and cover the same area (same longitudes and latitudes).

**Value**

An object of class bathy of the same dimensions as the original bathy objects contained within each buffer objects. The resulting bathy object contains only NAs outside of the combined buffer and values of depth/altitude inside the combined buffer.

**Author(s)**

Benoit Simon-Bouhet

**See Also**

[create.buffer](#), [plot.buffer](#), [plot.bathy](#)

**Examples**

```

# load and plot a bathymetry
data(florigida)
plot(florigida, lwd = 0.2)
plot(florigida, n = 1, lwd = 0.7, add = TRUE)

# add points around which a buffer will be computed
loc <- data.frame(c(-80,-82), c(26,24))
points(loc, pch = 19, col = "red")

# create 2 distinct buffer objects with different radii
buf1 <- create.buffer(florigida, loc[1,], radius=1.9)
buf2 <- create.buffer(florigida, loc[2,], radius=1.2)

# combine both buffers
buf <- combine.buffer(buf1,buf2)

## Not run:
# Add outline of the resulting buffer in red
# and the outline of the original buffers in blue
plot(outline.buffer(buf), lwd = 3, col = 2, add=TRUE)
plot(buf1, lwd = 0.5, fg="blue")
plot(buf2, lwd = 0.5, fg="blue")

## End(Not run)

```

---

create.buffer

---

*Create a buffer of specified radius around one or several points*

---

**Description**

Create a circular buffer of user-defined radius around one or several points defined by their longitudes and latitudes.

**Usage**

```
create.buffer(x, loc, radius, km = FALSE)
```

**Arguments**

x	an object of class bathy
loc	a 2-column data.frame of longitudes and latitudes for points around which the buffer is to be created.
radius	numeric. Radius of the buffer in the same unit as the bathy object (i.e. usually decimal degrees) when km=FALSE (default) or in kilometers when radius=TRUE.
km	logical. If TRUE, the radius should be provided in kilometers. When FALSE (default) the radius is in the same unit as the bathy object (i.e. usually decimal degrees).

**Details**

This function takes advantage of the buffer function from package adehabitatMA and several functions from packages sp to define the buffer around the points provided by the user.

**Value**

An object of class bathy of the same size as mat containing only NAs outside of the buffer and values of depth/altitude (taken from mat) within the buffer.

**Author(s)**

Benoit Simon-Bouhet

**See Also**

[outline.buffer](#), [combine.buffer](#), [plot.bathy](#)

**Examples**

```
# load and plot a bathymetry
data(florida)
plot(florida, lwd = 0.2)
plot(florida, n = 1, lwd = 0.7, add = TRUE)

# add a point around which a buffer will be created
loc <- data.frame(-80, 26)
points(loc, pch = 19, col = "red")

# compute and print buffer
buf <- create.buffer(florida, loc, radius=1.5)
buf

# highlight isobath with the buffer and add outline
plot(buf, outline=FALSE, n = 10, col = 2, lwd=.4)
plot(buf, lwd = 0.7, fg = 2)
```

---

diag.bathy

*Finds matrix diagonal for non-square matrices*

---

**Description**

Finds either the values of the coordinates of the non-linear diagonal of non-square matrices.

**Usage**

```
diag.bathy(mat, coord=FALSE)
```

**Arguments**

mat                    a data matrix  
coord                  whether of not to output the coordinates of the diagonal (default is FALSE)

**Details**

diag.bathy gets the values or coordinates from the first element of a matrix to its last elements. If the matrix is non-square, that is, its number of rows and columns differ, diag.bathy computes an approximate diagonal.

**Value**

A vector of diagonal values if coord is FALSE, or a table of diagonal coordinates if coord is TRUE

**Author(s)**

Eric Pante

**See Also**

[get.transect](#), [diag](#)

**Examples**

```
# a square matrix: diag.bathy behaves as diag
matrix(1:25, 5, 5) -> a ; a
diag(a)
diag.bathy(a)

# a non-square matrix: diag.bathy does not behaves as diag
matrix(1:15, 3, 5) -> b ; b
diag(b)
diag.bathy(b)

# output the diagonal or its coordinates:
rownames(b) <- seq(32,35, length.out=3)
colnames(b) <- seq(-100,-95, length.out=5)
diag.bathy(b, coord=FALSE)
diag.bathy(b, coord=TRUE)
```

---

dist2isobath	<i>Computes the shortest great circle distance between any point and a given isobath</i>
--------------	--

---

### Description

Computes the shortest (great circle) distance between a set of points and an isoline of depth or altitude. Points can be selected interactively by clicking on a map.

### Usage

```
dist2isobath(mat, x, y=NULL, isobath=0, locator=FALSE, ...)
```

### Arguments

mat	Bathymetric data matrix of class bathy, as imported with read.bathy.
x	Either a list of two elements (numeric vectors of longitude and latitude), a 2-column matrix or data.frame of longitudes and latitudes, or a numeric vector of longitudes.
y	Either NULL (default) or a numerical vector of latitudes. Ignored if x is not a numeric vector.
isobath	A single numerical value indicating the isobath to which the shortest distance is to be computed (default is set to 0, <i>i.e.</i> the coastline).
locator	Logical. Whether to choose data points interactively with a map or not. If TRUE, a bathymetric map must have been plotted and both x and y are both ignored.
...	Further arguments to be passed to locator when the interactive mode is used (locator=TRUE).

### Details

dist2isobath allows the user to compute the shortest great circle distance between a set of points (selected interactively on a map or not) and a user-defined isobath. dist2isobath takes advantage of functions from packages sp (Lines() and SpatialLines()) and geosphere (dist2Line) to compute the coordinates of the nearest location along a given isobath for each point provided by the user.

### Value

A 5-column data.frame. The first column contains the distance in meters between each point and the nearest point located on the given isobath. Columns 2 and 3 indicate the longitude and latitude of starting points (*i.e.* either coordinates provided as x and y or coordinates of points selected interactively on a map when locator=TRUE) and columns 4 and 5 contains coordinates (longitudes and latitudes) arrival points *i.e.* the nearest points on the isobath.

---

etopo

*Etopo colours*

---

**Description**

Various ways to access the colors on the etopo color scale

**Usage**

```
etopo.colors(n)

scale_fill_etopo(...)
scale_color_etopo(...)
```

**Arguments**

`n` number of colors to get from the scale. Those are evenly spaced within the scale.  
`...` passed to `scale_fill_gradientn` or `scale_color_gradientn`

**Details**

`etopo.colors` is equivalent to other color scales in R (e.g. `grDevices::heat.colors`, `grDevices::cm.colors`).  
`scale_fill/color_etopo` are meant to be used with `ggplot2`. They allow consistent plots in various subregions by setting the limits of the scale explicitly.

  geom_contour(aes(z=z),
    breaks=c(0, -100, -200, -500, -1000, -2000, -4000),
    colour="black", size=0.2
  ) +
  scale_x_continuous(expand=c(0,0)) +
  scale_y_continuous(expand=c(0,0))
```

---

florida

*Bathymetric data around Florida, USA*

---

**Description**

Bathymetric object of class bathy created from NOAA GEODAS data.

**Usage**

```
data(florida)
```

**Details**

Data imported from the NOAA GEODAS Grid Translator webpage (<https://maps.ngdc.noaa.gov/viewers/wcs-client/>) and transformed into an object of class bathy by read.bathy.

**Value**

A bathymetric object of class bathy with 539 rows and 659 columns.

**Author(s)**

see <https://maps.ngdc.noaa.gov/viewers/wcs-client/>

**See Also**

[plot.bathy](#), [summary.bathy](#)

**Examples**

```
# load florida data
data(florida)

# class "bathy"
class(florida)
summary(florida)

# test plot.bathy
plot(florida, asp=1)
plot(florida, asp=1, image=TRUE, drawlabels=TRUE, land=TRUE, n=40)
```

---

fortify.bathy

*Extract bathymetry data in a data.frame*

---

**Description**

Extract bathymetry data in a data.frame

**Usage**

```
## S3 method for class 'bathy'
fortify(x, ...)
```

**Arguments**

x                    bathymetric data matrix of class bathy, imported using [read.bathy](#)  
...                    ignored

**Details**

fortify.bathy is really just calling [as.xyz](#) and ensuring consistent names for the columns. It then allows to use ggplot2 functions directly.

**Author(s)**

Jean-Olivier Irisson

**See Also**

[autoplot.bathy](#), [as.xyz](#)

**Examples**

```
# load NW Atlantic data and convert to class bathy
data(nw.atlantic)
atl <- as.bathy(nw.atlantic)

library("ggplot2")
# convert bathy object into a data.frame
head(fortify(atl))

# one can now use bathy objects with ggplot directly
ggplot(atl) + geom_contour(aes(x=x, y=y, z=z)) + coord_map()

# which allows complete plot configuration
atl.df <- fortify(atl)
ggplot(atl.df, aes(x=x, y=y)) + coord_quickmap() +
  geom_raster(aes(fill=z), data=atl.df[atl.df$z <= 0,]) +
  geom_contour(aes(z=z),
    breaks=c(-100, -200, -500, -1000, -2000, -4000),
    colour="white", size=0.1
  ) +
  scale_x_continuous(expand=c(0,0)) +
  scale_y_continuous(expand=c(0,0))
```

---

get.area

*Get projected surface area*

---

**Description**

Get projected surface area for specific depth layers

**Usage**

```
get.area(mat, level.inf, level.sup=0, xlim=NULL, ylim=NULL)
```

## Arguments

mat	bathymetric data matrix of class bathy, imported using read.bathy (no default)
level.inf	lower depth limit for calculation of projected surface area (no default)
level.sup	upper depth limit for calculation of projected surface area (default is zero)
xlim	longitudinal range of the area of interest (default is NULL)
ylim	latitudinal range of the area of interest (default is NULL)

## Details

get.area calculates the projected surface area of specific depth layers (e.g. upper bathyal, lower bathyal), the projected plane being the ocean surface. The resolution of get.area depends on the resolution of the input bathymetric data. xlim and ylim can be used to restrict the area of interest. Area calculation is based on areaPolygon of package geosphere (using an average Earth radius of 6,371 km).

## Value

A list of four objects: the projected surface area in squared kilometers, a matrix with the cells used for calculating the projected surface area, the longitude and latitude of the matrix used for the calculations.

```

---

get.box

*Get bathymetric information of a belt transect*

---

### Description

get.box gets depth information of a belt transect of width width around a transect defined by two points on a bathymetric map.

### Usage

```
get.box(bathy,x1,x2,y1,y2,width,locator=FALSE,ratio=FALSE, ...)
```

**Arguments**

bathy	Bathymetric data matrix of class bathy.
x1	Numeric. Start longitude of the transect. Requested when locator=FALSE.
x2	Numeric. Stop longitude of the transect. Requested when locator=FALSE.
y1	Numeric. Start latitude of the transect. Requested when locator=FALSE.
y2	Numeric. Stop latitude of the transect. Requested when locator=FALSE.
width	Numeric. Width of the belt transect in degrees.
locator	Logical. Whether to choose transect bounds interactively with a map or not. When FALSE (default), a bathymetric map ( <code>plot.bathy(bathy, image=TRUE)</code> ) is automatically plotted and the position of the belt transect is added.
ratio	Logical. Should aspect ratio for the wireframe plotting function (package <code>lattice</code> ) be computed (default is FALSE).
...	Other arguments to be passed to <code>locator</code> and <code>lines</code> to specify the characteristics of the points and lines to draw on the bathymetric map for both the transect and the bounding box of belt transect.

**Details**

`get.box` allows the user to get depth data for a rectangle area of the map around an approximate linear transect (belt transect). Both the position and size of the belt transect are user defined. The position of the transect can be specified either by inputting start and stop coordinates, or by clicking on a map created with `plot.bathy`. In its interactive mode, this function uses the `locator` function (`graphics` package) to retrieve and plot the coordinates of the selected transect. The argument `width` allows the user to specify the width of the belt transect in degrees.

**Value**

A matrix containing depth values for the belt transect. `rownames` indicate the kilometric distance from the start of the transect and `colnames` indicate the distance from the central transect in degrees. If `ratio=TRUE`, a list of two elements: `depth`, a matrix containing depth values for the belt transect similar to the description above and `ratios` a vector of length two specifying the ratio between (i) the width and length of the belt transect and (ii) the depth range and the length of the belt transect. These ratios can be used by the function `wireframe` to produce realistic 3D bathymetric plots of the selected belt transect.

**Author(s)**

Benoit Simon-Bouhet and Eric Pante

**Examples**

```

# load and plot bathymetry
data(hawaii)
plot(hawaii,im=TRUE)

# get the depth matrix for a belt transect
depth <- get.box(hawaii,x1=-157,y1=20,x2=-155.5,y2=21,width=0.5,col=2)

# plotting a 3D bathymetric map of the belt transect
require(lattice)
wireframe(depth,shade=TRUE)

# get the depth matrix for a belt transect with realistic aspect ratios
depth <- get.box(hawaii,x1=-157,y1=20,x2=-155.5,y2=21,width=0.5,col=2,ratio=TRUE)

# plotting a 3D bathymetric map of the belt transect with realistic aspect ratios
require(lattice)
wireframe(depth[[1]],shade=TRUE,aspect=depth[[2]])

```

---

get.depth

*Get depth data by clicking on a map*

---

**Description**

Outputs depth information based on points selected by clicking on a map

**Usage**

```
get.depth(mat, x, y=NULL, locator=TRUE, distance=FALSE, ...)
```

**Arguments**

mat	Bathymetric data matrix of class bathy, as imported with read.bathy.
x	Either a list of two elements (numeric vectors of longitude and latitude), a 2-column matrix or data.frame of longitudes and latitudes, or a numeric vector of longitudes.
y	Either NULL (default) or a numerical vector of latitudes. Ignored if x is not a numeric vector.
locator	Logical. Whether to choose data points interactively with a map or not. If TRUE (default), a bathymetric map must have been plotted and both x and y are both ignored.
distance	whether to compute the haversine distance (in km) from the first data point on (default is FALSE). Only available when at least two points are provided.
...	Further arguments to be passed to locator when the interactive mode is used (locator=TRUE).

**Details**

`get.depth` allows the user to get depth data by clicking on a map created with `plot.bathy` or by providing coordinates of points of interest. This function uses the `locator` function (graphics package); after creating a map with `plot.bathy`, the user can click on the map once or several times (if `locator=TRUE`), press the Escape button, and get the depth of those locations in a three-column `data.frame` (longitude, latitude and depth). Alternatively, when `locator=FALSE`, the user can submit a list of longitudes and latitudes, a two-column matrix or `data.frame` of longitudes and latitudes (as input for `x`), or one vector of longitudes (`x`) and one vector of latitudes (`y`). The non-interactive mode is well suited to get depth information for each point provided by GPS tracking devices. While `get.transect` gets every single depth value available in the bathymetric matrix between two points along a user-defined transect, `get.depth` only provides depth data for the specific points provided as input by the user.

**Value**

A `data.frame` with at least, longitude, latitude and depth with one line for each point of interest. If `distance=TRUE`, a fourth column containing the kilometric distance from the first point is added.

**Author(s)**

Benoit Simon-Bouhet and Eric Pante

**Examples**

```
# load NW Atlantic data and convert to class bathy
data(nw.atlantic)
atl <- as.bathy(nw.atlantic)

# create vectors of latitude and longitude
lon <- c(-70, -65, -63, -55)
lat <- c(33, 35, 40, 37)

# a simple example
plot(atl, lwd=.5)
points(lon,lat,pch=19,col=2)

# Use get.depth to get the depth for each point
get.depth(atl, x=lon, y=lat, locator=FALSE)

# alternatively once the map is plotted, use the interactive mode:
## Not run:
get.depth(atl, locator=TRUE, pch=19, col=3)

## End(Not run)
# click several times and press Escape
```

---

`get.sample`*Get sample data by clicking on a map*

---

**Description**

Outputs sample information based on points selected by clicking on a map

**Usage**

```
get.sample(mat, sample, col.lon, col.lat, ...)
```

**Arguments**

<code>mat</code>	bathymetric data matrix of class <code>bathy</code> , imported using <code>read.bathy</code> (no default)
<code>sample</code>	<code>data.frame</code> containing sampling information (at least longitude and latitude) (no default)
<code>col.lon</code>	column number of data frame <code>sample</code> containing longitude information (no default)
<code>col.lat</code>	column number of data frame <code>sample</code> containing latitude information (no default)
<code>...</code>	further arguments to be passed to <code>rect</code> for drawing a box around the selected area

**Details**

`get.sample` allows the user to get sample data by clicking on a map created with `plot.bathy`. This function uses the `locator` function (`graphics` package). After creating a map with `plot.bathy`, the user can click twice on the map to delimit an area (for example, lower left and upper right corners of a rectangular area of interest), and get a dataframe corresponding to the sample points present within the selected area.

**Value**

a dataframe of the elements of `sample` present within the area selected

**Warning**

clicking once or more than twice on the map will return a warning message: "Please choose two points from the map"

**Author(s)**

Eric Pante

**Examples**

```
## Not run:
# load metallo sampling data and add a third field containing a specimen ID
data(metallo)
metallo$id <- factor(paste("Metallo",1:38))

# load NW Atlantic data, convert to class bathy, and plot
data(nw.atlantic)
atl <- as.bathy(nw.atlantic)
plot(atl, deep=-8000, shallow=0, step=1000, col="grey")

# once the map is plotted, use get.sample to get sampling info!
get.sample(atl, metallo, 1, 2)
# click twice

## End(Not run)
```

---

get.transect

---

*Compute approximate cross section along a depth transect*

---

**Description**

Compute the depth along a linear transect which bounds are specified by the user.

**Usage**

```
get.transect(mat, x1, y1, x2, y2, locator=FALSE, distance=FALSE, ...)
```

**Arguments**

mat	bathymetric data matrix of class bathy, imported using read.bathy (no default)
x1	start longitude of the transect (no default)
x2	stop longitude of the transect (no default)
y1	start latitude of the transect (no default)
y2	stop latitude of the transect (no default)
locator	whether to use locator to choose transect bounds interactively with a map (default is FALSE)
distance	whether to compute the haversine distance (in km) from the start of the transect, along the transect (default is FALSE)
...	other arguments to be passed to locator() to specify the characteristics of the points and lines to draw on the bathymetric map when locator=TRUE.

**Details**

get.transect allows the user to compute an approximate linear depth cross section either by inputting start and stop coordinates, or by clicking on a map created with plot.bathy. In its interactive mode, this function uses the locator function (graphics package); after creating a map with plot.bathy, the user can click twice to delimit the bound of the transect of interest (for example, lower left and upper right corners of a rectangular area of interest), press Escape, and get a table with the transect information.

**Value**

A table with, at least, longitude, latitude and depth along the transect, and if specified (distance=TRUE), the distance in kilometers from the start of the transect. The number of elements in the resulting table depends on the resolution of the bathy object.

**Warning**

Clicking once or more than twice on the map will return a warning message: "Please choose only two points from the map". Manually entering coordinates that are outside the geographical range of the input bathy matrix will return a warning message.

**Note**

The distance option of get.transect is calculated based on the haversine formula for getting the great circle distance (takes into account the curvature of the Earth). get.transect uses an internal function called diag.bathy that extracts the approximate diagonal of a matrix, when that matrix has uneven dimensions (different numbers of columns and rows).

plotProfile(test)

## End(Not run)

```

---

getNOAA.bathy

---

*Import bathymetric data from the NOAA server*

---

## Description

Imports bathymetric data from the NOAA server, given coordinate bounds and resolution.

## Usage

```

getNOAA.bathy(lon1, lon2, lat1, lat2, resolution = 4,
              keep = FALSE, antimeridian = FALSE, path = NULL)

```

## Arguments

lon1	first longitude of the area for which bathymetric data will be downloaded
lon2	second longitude of the area for which bathymetric data will be downloaded
lat1	first latitude of the area for which bathymetric data will be downloaded
lat2	second latitude of the area for which bathymetric data will be downloaded
resolution	resolution of the grid, in minutes (default is 4)
keep	whether to write the data downloaded from NOAA into a file (default is FALSE)
antimeridian	whether the area should include the antimeridian (longitude 180 or -180). See details.
path	Where should bathymetric data be downloaded to if keep = TRUE? Where should getNOAA.bathy() look up for bathymetric data already downloaded? Defaults to the current working directory.

## Details

getNOAA.bathy queries the ETOPO1 database hosted on the NOAA website, given the coordinates of the area of interest and desired resolution. Users have the option of directly writing the downloaded data into a file (keep = TRUE argument ; see below). If an identical query is performed (i.e. using identical lat-long and resolution), getNOAA.bathy will load data from the file previously written to the disk instead of querying the NOAA database. This behavior should be used preferentially (1) to reduce the number of unnecessary queries to the NOAA website, and (2) to reduce data load time. If the user wants to make multiple, identical queries to the NOAA website without loading the data written to disk, the data file name must be modified by the user. Alternatively, the data file can be moved outside of the present working directory.

getNOAA.bathy allows users to download bathymetric data in the antimeridian region when antimeridian=TRUE. The antimeridian is the 180th meridian and is located about in the middle of the Pacific Ocean, east of New Zealand and Fiji, west of Hawaii and Tonga. For a given pair of longitude values, e.g. -150 (150 degrees West) and 150 (degrees East), you have the possibility to get data for 2 distinct regions: the area centered on the antimeridian (60 degrees wide, when antimeridian = TRUE) or the area centered on the prime meridian (300 degrees wide, when antimeridian = FALSE). It is recommended to use keep = TRUE in combination with antimeridian = TRUE since gathering data for an area around the antimeridian requires two distinct queries to NOAA servers.

## Value

The output of getNOAA.bathy is a matrix of class bathy, which dimensions depends on the resolution of the grid uploaded from the NOAA server. The class bathy has its own methods for summarizing and plotting the data. If keep=TRUE, a csv file containing the downloaded data is produced. This file is named using the following format: 'marmap\_coord\_COORDINATES\_res\_RESOLUTION.csv' (COORDINATES separated by semicolons, and the RESOLUTION in degrees).

---

**griddify***Fill a grid with irregularly spaced data*

---

### Description

Transforms irregularly spaced xyz data into a raster object suitable to create a bathy object with regularly spaced longitudes and latitudes.

### Usage

```
griddify(xyz, nlon, nlat)
```

### Arguments

xyz	3-column matrix or data.frame containing (in this order) arbitrary longitude, latitude and altitude/depth values.
nlon	integer. The number of unique regularly-spaced longitude values that will be used to create the grid.
nlat	integer. The number of unique regularly-spaced latitude values that will be used to create the grid.

### Details

griddify takes any dataset with irregularly spaced xyz data and transforms it into a raster object (i.e. a grid) with user specified dimensions. griddify relies on several functions from the raster package, especially rasterize and resample. If a cell of the user-defined grid does not contain any depth/altitude value in the original xyz matrix/data.frame, a NA is added in that cell. A bilinear interpolation is then applied in order to fill in most of the missing cells. For cells of the user-defined grid containing more than one depth/altitude value in the original xyz matrix/data.frame, the mean depth/altitude value is computed.

### Value

The output of griddify is an object of class raster, with nlon unique longitude values and nlat unique latitude values.

---

hawaii

*Bathymetric data for Hawaii, USA*

---

## Description

Bathymetric object of class `bathy` created from NOAA GEODAS data and arbitrary locations around the main Hawaiian islands.

## Usage

```
data(hawaii)
data(hawaii.sites)
```

## Details

`hawaii` contains data imported from the NOAA GEODAS Grid Translator webpage (<https://maps.ngdc.noaa.gov/viewers/wcs-client/>) and transformed into an object of class `bathy` by `read.bathy`. `hawaii.sites` is a 2-columns `data.frame` containing longitude and latitude of 6 locations spread at sea around Hawaii.

**Value**

hawaii: a bathymetric object of class bathy with 539 rows and 659 columns. hawaii.sites: data.frame (6 rows, 2 columns)

**Author(s)**

see <https://maps.ngdc.noaa.gov/viewers/wcs-client/>

**See Also**

irregular

*Irregularly spaced bathymetric data.*

---

**Description**

Three-column data.frame of irregularly-spaced longitudes, latitudes and depths.

**Usage**

```
data(irregular)
```

**Value**

A three-columns data.frame containing longitude, latitude and depth/elevation data.

**Author(s)**

Data modified form a dataset kindly provided by Noah Lottig from the university of Wisconsin <https://limnology.wisc.edu/staff/lottig-noah/> in the framework of the North Temperate Lakes Long Term Ecological Research program <https://lter.limnology.wisc.edu>

**See Also**

**Examples**

```
# load data
data(irregular)

# use griddify
reg <- griddify(irregular, nlon = 40, nlat = 60)

# switch to class "bathy"
class(reg)
bat <- as.bathy(reg)
summary(bat)

# Plot the new bathy object along with the original data
plot(bat, image = TRUE, lwd = 0.1)
points(irregular$lon, irregular$lat, pch = 19, cex = 0.3, col = col2alpha(3))
```

---

is.bathy

*Test whether an object is of class bathy*

---

**Description**

Test whether an object is of class bathy

**Usage**

```
is.bathy(xyz)
```

**Arguments**

xyz                    three-column data.frame with longitude (x), latitude (y) and depth (z) (no default)

**Value**

The function returns TRUE or FALSE

**Author(s)**

Eric Pante

---

`lc.dist`*Computes least cost distances between two or more locations*

---

**Description**

Computes least cost distances between two or more locations

**Usage**

```
lc.dist(trans, loc, res=c("dist", "path"))
```

**Arguments**

<code>trans</code>	transition object as computed by <code>trans.mat</code>
<code>loc</code>	A two-columns matrix or data.frame containing latitude and longitude for 2 or more locations.
<code>res</code>	either "dist" or "path". See details.

**Details**

`lc.dist` computes least cost distances between 2 or more locations. This function relies on the package `gdistance` (van Etten, 2011. <https://CRAN.R-project.org/package=gdistance>) and on the `trans.mat` function to define a range of depths where the paths are possible.

**Value**

Results can be presented either as a kilometric distance matrix between all possible pairs of locations (argument `res="dist"`) or as a list of paths (i.e. 2-columns matrices of routes) between pairs of locations (`res="path"`).

**Author(s)**

Benoit Simon-Bouhet

**References**

Jacob van Etten (2011). `gdistance`: distances and routes on geographical grids. R package version 1.1-2. <https://CRAN.R-project.org/package=gdistance>

## End(Not run)

```

---

linesGC                      *Add Great Circle lines on a map*

---

### Description

linesGC draws Great Circle lines between a set of start and end points on an existing map.

### Usage

```
linesGC(start.points, end.points, n = 10, antimeridian = FALSE, ...)
```

### Arguments

start.points	Two-column data.frame or matrix of longitudes and latitudes for start points.
end.points	Two-column data.frame or matrix of longitudes and latitudes for end points. The dimensions of start.points and end.points must be compatible ( <i>i.e.</i> they must have the same number of rows).
n	Numeric. The number of intermediate points to add along the great circle line between the start end end points.
antimeridian	Logical indicating if the map on which the great circle lines will be plotted covers the antimeridian region. The antimeridian (or antemeridian) is the 180th meridian and is located in the middle of the Pacific Ocean, east of New Zealand and Fidji, west of Hawaii and Tonga.
...	Further arguments to be passed to lines to control the aspect of the lines to draw.

### Details

linesGCD takes advantage of the gcIntermediate function from package geosphere to plot lines following a great circle. When working with marmap maps encompassing the antimeridian, longitudes are numbered from 0 to 360 (as opposed to the classical numbering from -180 to +180). It is thus critical to set antimeridian=TRUE to avoid plotting incoherent great circle lines.

marmap

---

*Import, plot and analyze bathymetric and topographic data*

---

**Description**

marmap is a package designed for downloading, plotting and manipulating bathymetric and topographic data in R. It can query the ETOPO1 bathymetry and topography database hosted by the

NOAA, use simple latitude-longitude-depth data in ascii format, and take advantage of the advanced plotting tools available in R to build publication-quality bathymetric maps. Functions to query data (bathymetry, sampling information, etc...) are available interactively by clicking on marmap maps. Bathymetric and topographic data can also be used to calculate projected surface areas within specified depth/altitude intervals, and constrain the calculation of realistic shortest path distances.

---

`nw.atlantic`*Bathymetric data for the North West Atlantic*

---

**Description**

Data imported from the NOAA GEODAS server

**Usage**

```
data(nw.atlantic)
```

**Details**

Data imported from the NOAA GEODAS Grid Translator webpage (<https://maps.ngdc.noaa.gov/viewers/wcs-client/>). To prepare data from NOAA, fill the custom grid form, and choose "XYZ (lon,lat,depth)" as the "Output Grid Format", "No Header" as the "Output Grid Header", and either of the space, tab or comma as the column delimiter (either can be used, but "comma" is the default import format of `read.bathy`). Choose "omit empty grid cells" to reduce memory usage.

**Value**

A three-columns data.frame containing longitude, latitude and depth/elevation data.

**Author(s)**

see <https://maps.ngdc.noaa.gov/viewers/wcs-client/>

```

---

outline.buffer	<i>Get a composite buffer in a format suitable for plotting its outline</i>
----------------	---

---

### Description

Get a buffer (i.e. a non-circular buffer as produced by `combine.buffers()`) in a format suitable for plotting its outline. `outline.buffer()` replaces any NA values in a buffer or bathy object by 0 and non-NA values by -1.

### Usage

```
outline.buffer(buffer)
```

### Arguments

buffer	a buffer object of class bathy (i.e. bathy matrix containing depth/altitude values within the buffer and NAs outside)
--------	---

### Details

This function is essentially used to prepare a composite buffer for plotting its outline on a bathymetric map. Plotting a single circular buffer should be done using the `plot.buffer()` function since it offers a more straightforward method for plotting and much smoother outlines, especially for low-resolution bathymetries.

### Value

An object of class bathy of the same dimensions as `buffer` containing only zeros (outside the buffer area) and -1 values (within the buffer).

### Author(s)

Benoit Simon-Bouhet

### See Also

[create.buffer](#), [combine.buffers](#), [plot.bathy](#)

**Examples**

```

# load and plot a bathymetry
data(flórida)
plot(flórida, lwd = 0.2)
plot(flórida, n = 1, lwd = 0.7, add = TRUE)

# add points around which a buffer will be computed
loc <- data.frame(c(-80,-82), c(26,24))
points(loc, pch = 19, col = "red")

# create 2 distinct buffer objects with different radii
buf1 <- create.buffer(flórida, loc[1,], radius=1.9)
buf2 <- create.buffer(flórida, loc[2,], radius=1.2)

# combine both buffers
buf <- combine.buffers(buf1,buf2)

## Not run:
# Add outline of the resulting buffer in red
# and the outline of the original buffers in blue
plot(outline.buffer(buf), lwd = 3, col = 2, add=TRUE)
plot(buf1, lwd = 0.5, fg="blue")
plot(buf2, lwd = 0.5, fg="blue")

## End(Not run)

```

---

palette.bathy

*Builds a bathymetry- and/or topography-constrained color palette*

---

**Description**

Builds a constrained color palette based on depth / altitude bounds and given colors.

**Usage**

```
palette.bathy(mat, layers, land=FALSE, default.col="white")
```

**Arguments**

mat	a matrix of bathymetric data, class bathy not required.
layers	a list of depth bounds and colors (see below)
land	logical. Whether to consider land or not (default is FALSE)
default.col	a color for the area of the matrix not bracketed by the list supplied to layers

**Details**

`palette.bathy` allows the production of color palettes for specified bathymetric and/or topographic layers. The `layers` argument must be a list of vectors. Each vector corresponds to a bathymetry/topography layer (for example, one layer for bathymetry and one layer for topography). The first and second elements of the vector are the minimum and maximum bathymetry/topography, respectively. The other elements of the vector (3, onward) correspond to colors (see example below). `palette.bathy` is called internally by `plot.bathy` when the `image` argument is set to `TRUE`.

**Value**

A vector of colors which size depends on the depth / altitude range of the bathy matrix.

**Author(s)**

Eric Pante and Benoit Simon-Bouhet

```

---

path.profile

*Geographic coordinates, kilometric distance and depth along a path*

---

## Description

Computes and plots the depth/altitude along a transect or path

## Usage

```
path.profile(path,bathy,plot=FALSE, ...)
```

## Arguments

path	2-columns matrix of longitude and latitude as obtained from <code>lc.dist</code> with argument <code>dist=TRUE</code> .
bathy	bathymetric data matrix of class <code>bathy</code> .
plot	logical. Should the depth profile be plotted?
...	when <code>plot=TRUE</code> , other arguments to be passed to <code>plotProfile</code> , such as <a href="#">graphical parameters</a> (see <a href="#">par</a> and <a href="#">plotProfile</a> ).

## Value

a four-columns matrix containing longitude, latitude, kilometric distance from the start of a route and depth for a set of points along a route. Optionally (i.e. when `plot=TRUE`) a bivariate plot of depth against the kilometric distance from the starting point of a transect or least cost path.

## Author(s)

Benoit Simon-Bouhet

summary(profile)

```

plot.bathy

*Plotting bathymetric data***Description**

Plots contour map from bathymetric data matrix of class bathy

**Usage**

```

## S3 method for class 'bathy'
plot(x, image=FALSE, bpal=NULL, land=FALSE,
      deepest.isobath, shallowest.isobath, step, n=20,
      lwd=1, lty=1, col="black", default.col="white", drawlabels = FALSE,
      xlab="Longitude", ylab="Latitude", asp=1, ...)

```

**Arguments**

x	bathymetric data matrix of class bathy, imported using read.bathy
image	whether or not to color depth layers (default is FALSE)
bpal	if image is TRUE, either NULL (default: a simple blue color palette is used), a vector of colors, or a list of depth bounds and colors (see below)
land	whether or not to use topographic data that may be available in the bathy dataset (default is FALSE)

deepest.isobath	deepest isobath(s) to plot
shallowest.isobath	shallowest isobath(s) to plot
step	distance(s) between two isobaths
n	if the user does not specify the range within which isobaths should be plotted, about n isobaths are automatically plotted within the depth range of the bathy matrix (default is 20).
lwd	isobath line(s) width (default is 1)
lty	isobath line type(s) (default is 1)
col	isobath line color(s) (default is black)
default.col	if image is TRUE, a color for the area of the matrix not bracketed by the list supplied to bpal (see below; default is white)
drawlabels	whether or not to plot isobath depth as a label (default is FALSE); may contain several elements
xlab	label for the x axis of the plot
ylab	label for the y axis of the plot
asp	numeric, giving the aspect ratio y/x of the plot. See <a href="#">plot.window</a>
...	Other arguments to be passed either to countour (default) or to image when argument image=TRUE.

### Details

plot.bathy uses the base contour and image functions. If a vector of isobath characteristics is provided, different types of isobaths can be added to the same plot using a single call of plot.bathy (see examples)

If image=TRUE, the user has three choices for colors: (1) bpal can be set to NULL, in which case a default blue color palette is generated; (2) colors can be user-defined as in example 4, in which case the palette can be generated with function colorRampPalette (colors are then supplied as a vector to plot.bathy) ; (3) colors can be constrained to bathymetry- and/or topography. In this last case, a list of vectors is supplied to plot.bathy (example 7): each vector corresponds to a bathymetry/topography layer (for example, one layer for bathymetry and one layer for topography). The first and second elements of the vector are the minimum and maximum bathymetry/topography, respectively. The other elements of the vector (3, onward) correspond to colors (see example 7).

### Value

a bathymetric map with isobaths

### Note

plot.bathy uses a matrix of class bathy, and can therefore be substituted for plot.

### Author(s)

## Examples

```
# load NW Atlantic data and convert to class bathy
data(nw.atlantic)
atl <- as.bathy(nw.atlantic)

## Example 1: a simple marine chart
plot(atl) # without specifying any isobath parameters
plot(atl, n=5, drawlabels=TRUE) # with about 5 isobaths
plot(atl, deep=-8000, shallow=0, step=1000) # with isobath parameters

## Example 2: taking advantage of multiple types of isobaths
plot(atl, deep=c(-8000,-2000,0), shallow=c(-2000,-100,0), step=c(1000,100,0),
     lwd=c(0.5,0.5,1),lty=c(1,1,1),col=c("grey80","red", "blue"),
     drawlabels=c(FALSE,FALSE,FALSE) )

## Example 3: plotting a colored map with the default color palette
plot(atl, image=TRUE, deep=c(-8000,0), shallow=c(-1000,0), step=c(1000,0),
     lwd=c(0.5,1), lty=c(1,1), col=c("grey","black"), drawlabels=c(FALSE,FALSE))

## Example 4: make a pretty custom color ramp
colorRampPalette(c("purple","lightblue","cadetblue2","cadetblue1","white")) -> blues

plot(atl, image=TRUE, bpal=blues(100), deep=c(-6500,0), shallow=c(-50,0), step=c(500,0),
     lwd=c(0.3,1), lty=c(1,1), col=c("black","black"), drawlabels=c(FALSE,FALSE))

scaleBathy(atl, deg=3, x="bottomleft", inset=5)

## Example 5: add points corresponding to sampling locations
##           point colors correspond to the sampling depth
par(mai=c(1,1,1,1.5))
plot(atl, deep=c(-4500,0), shallow=c(-50,0), step=c(500,0),
     lwd=c(0.3,1), lty=c(1,1), col=c("black","black"), drawlabels=c(FALSE,FALSE))

# add a title to the plot
title(main="Distribution of coral samples\non the New England and Corner Rise seamounts")
# add a scale
scaleBathy(atl, deg=3, x="bottomleft", inset=5)

# add a geographical reference on the coast:
points(-71.064,42.358, pch=19)
text(-71.064,42.358,"Boston", adj=c(1.2,0))
```

```

# prepare colors for the sampling locations:
data(metallo) ## see dataset metallo
max(metallo$depth, na.rm=TRUE) -> mx
colorRampPalette(c("white","lightyellow","lightgreen","blue","lightblue1","purple")) -> ramp
blues <- ramp(max(metallo$depth))

# plot sampling locations:
points(metallo, col="black", bg=blues[metalloy$depth], pch=21,cex=1.5)
library(shape)
colorlegend(zlim=c(-mx,0), col=rev(blues), main="depth (m)",posx=c(0.85,0.88))

## Example 6: use packages maps and mapdata in combination with marmap
# use maps and mapdata to plot the coast
library(maps)
library(mapdata)
map('worldHires',xlim=c(-75,-46),ylim=c(32,44), fill=TRUE, col="grey")
box();axis(1);axis(2)

# add bathymetric data from 'bathy' data
plot(atl, add=TRUE, lwd=.3, deep=-4500, shallow=-10, step=500,
drawlabel=FALSE, col="grey50")

## Example 7: provide a list of depths and colors to argument bpal to finely tune palette
# check out ?palette.bathy to see details on how the palette is handled

# creating depth-constrained palette for the ocean only
plot(atl, land = FALSE, n = 10, lwd = 0.5, image = TRUE,
      bpal = list(c(min(atl), 0, "purple", "blue", "lightblue")),
      default.col = "gray")

# creating depth-constrained palette for 3 ocean "layers"
plot(atl, land = FALSE, n = 10, lwd = 0.7, image = TRUE,
      bpal = list(c(min(atl), -3000, "purple","blue","grey"),
                  c(-3000, -150, "white"),
                  c(-150, 0, "yellow", "green", "brown")),
      default.col = "grey")

# creating depth-constrained palette for land and ocean
plot(atl, land = TRUE, n = 10, lwd = 0.7, image = TRUE,
      bpal = list(c(min(atl), 0, "purple", "blue", "lightblue"),
                  c(0, max(atl), "gray90", "gray10")))

```

---

plot.buffer

*Plots a circular buffer and or its outline*

---

## Description

plot.buffer is a generic function that allows the plotting of objects of class buffer, either as new plots or as a new layer added on top of an existing one. The plotting of both the bathymetry/hypsometry as well as the outline of the buffer is possible.

**Usage**

```
## S3 method for class 'buffer'  
plot(x, outline = TRUE, add = TRUE, ...)
```

**Arguments**

x	an object of class buffer as produced by the create.buffer() function.
outline	Should the outline of the buffer be plotted (default) or the bathymetric/hypsometric data within the buffer.
add	Should the plot be added on top of an existing bathymetric/hypsometric plot (default) or as a new plot
...	Further arguments to be passed to the symbols() function from the graphics package when outline = TRUE (default) or to plot.bathy() when outline = FALSE.

**Value**

Either a plot of the outline of a buffer (default) or a bathymetric map with isobaths of a buffer when outline = FALSE

**Author(s)**

Benoit Simon-Bouhet

**Examples**

```
# load and plot a bathymetry  
data(florida)  
plot(florida, lwd = 0.2)  
plot(florida, n = 0, lwd = 0.7, add = TRUE)  
  
# add points around which a buffer will be computed  
loc <- data.frame(-80, 26)  
points(loc, pch = 19, col = "red")  
  
# compute buffer  
buf <- create.buffer(florida, loc, radius=1.5)  
  
# plot buffer bathymetry  
plot(buf, outline=FALSE, n=10, lwd=.5, col=2)  
  
# add buffer outline  
plot(buf, lwd=.7, fg=2)
```

---

plotArea	<i>Plotting projected surface areas</i>
----------	---

---

### Description

Highlights the projected surface area for specific depth layers on an existing bathymetric/hypsometric map

### Usage

```
plotArea(area, col)
```

### Arguments

area	a list of 4 elements as produced by <a href="#">get.area</a> .
col	color of the projected surface area on the map.

### Author(s)

Benoit Simon-Bouhet

### See Also

[get.area](#), [plot.bathy](#), [areaPolygon](#)

### Examples

```
# load and plot a bathymetry
data(florida)
plot(florida, lwd = 0.2)
plot(florida, n = 1, lwd = 0.7, add = TRUE)

# Create a point and a buffer around this point
loc <- data.frame(-80, 26)
buf <- create.buffer(florida, loc, radius=1.8)

# Get the surface within the buffer for several depth slices
surf1 <- get.area(buf, level.inf=-200, level.sup=-1)
surf2 <- get.area(buf, level.inf=-800, level.sup=-200)
surf3 <- get.area(buf, level.inf=-3000, level.sup=-800)

s1 <- round(surf1$Square.Km)
s2 <- round(surf2$Square.Km)
s3 <- round(surf3$Square.Km)

# Add buffer elements on the plot
col.surf1 <- rgb(0.7, 0.7, 0.3, 0.3)
col.surf2 <- rgb(0, 0.7, 0.3, 0.3)
col.surf3 <- rgb(0.7, 0, 0, 0.3)
```

```

plotArea(surf1, col = col.surf1)
plotArea(surf2, col = col.surf2)
plotArea(surf3, col = col.surf3)
plot(buf, lwd = 0.7)
points(loc, pch = 19, col = "red")

## Add legend
legend("topleft", fill = c(col.surf1, col.surf2, col.surf3),
      legend = c(paste("]-200 ; -1] -", s1, "km2"),
                paste("]-800 ; -200] -", s2, "km2"),
                paste("]-3000 ; -800] -", s3, "km2")))

```

---

plotProfile

*Plotting bathymetric data along a transect or path*

---

## Description

Plots the depth/altitude along a transect or path

## Usage

```
plotProfile(profile, shadow=TRUE, xlim, ylim, col.sea, col.bottom, xlab, ylab, ...)
```

## Arguments

profile	4-columns matrix obtained from <code>get.transect</code> with argument <code>dist=TRUE</code> , or from <code>path.profile</code> .
shadow	logical. Should the depth profile cast a shadow over the plot background?
xlim, ylim	numeric vectors of length 2, giving the x and y coordinates ranges. If unspecified, <code>xlim</code> values are based on the length of the transect or path and <code>ylim</code> values are based on the depth range of the bathymetric matrix <code>bathy</code> .
col.sea	color for the sea area of the plot. Defaults to <code>rgb(130/255, 180/255, 212/255)</code>
col.bottom	color for the bottom area of the plot. Defaults to <code>rgb(198/255, 184/255, 151/255)</code>
xlab, ylab	titles for the x and y axes. If unspecified, <code>xlab="Distance from start of transect (km)"</code> and <code>ylab="Depth (m)"</code>
...	arguments to be passed to methods, such as <a href="#">graphical parameters</a> (see <code>par</code> )

## Value

a bivariate plot of depth against the kilometric distance from the starting point of a transect or least cost path.

## Note

`path.profile` with argument `plot` set to `TRUE` plots depth profiles with default values for all arguments of `plotProfile`.

**Author(s)**

Benoit Simon-Bouhet

**See Also**[path.profile](#), [plot.bathy](#)**Examples**

```
# Example 1:
data(celt)
layout(matrix(1:2,nc=1),height=c(2,1))
par(mar=c(4,4,1,1))
plot(celt,n=40,draw=TRUE)
points(c(-6.34,-5.52),c(52.14,50.29),type="o",col=2)

tr <- get.transect(celt, x1 = -6.34, y1 = 52.14, x2 = -5.52, y2 = 50.29, distance = TRUE)
plotProfile(tr)

# Example 2:
layout(matrix(1:2,nc=1),height=c(2,1))
par(mar=c(4,4,1,1))
plot(celt,n=40,draw=TRUE)
points(c(-5,-6.34),c(49.8,52.14),type="o",col=2)

tr2 <- get.transect(celt, x1 = -5, y1 = 49.8, x2 = -6.34, y2 = 52.14, distance = TRUE)
plotProfile(tr2)

# Example 3: click several times on the map and press ESC
## Not run:

plot(florida,image=TRUE,dra=TRUE,land=TRUE,n=40)

out <- path.profile(as.data.frame(locator(type="o",col=2,pch=19,cex=.8)),florida)
plotProfile(out)

## End(Not run)
```

---

`read.bathy`*Read bathymetric data in XYZ format*

---

**Description**

Reads a three-column table containing longitude (x), latitude (y) and depth (z) data.

**Usage**

```
read.bathy(xyz, header = FALSE, sep = ",", ...)
```

**Arguments**

xyz	three-column table with longitude (x), latitude (y) and depth (z) (no default)
header	whether this table has a row of column names (default = FALSE)
sep	character separating columns, (default=",")
...	further arguments to be passed to read.table()

**Details**

Allows direct import of data from the NOAA GEODAS Grid Translator webpage (<https://maps.ngdc.noaa.gov/viewers/wcs-client/>). To prepare data from NOAA, fill the custom grid form, and choose "XYZ (lon,lat,depth)" as the "Output Grid Format", "No Header" as the "Output Grid Header", and either of the space, tab or comma as the column delimiter (either can be used, but "comma" is the default import format of read.bathy). Choose "omit empty grid cells" to reduce memory usage.

**Value**

The output of read.bathy is a matrix of class bathy, which dimensions depends on the resolution of the grid uploaded from the NOAA GEODAS server (Grid Cell Size). The class bathy has its own methods for summarizing and plotting the data.

# class "bathy"
class(atl)
```

```
# summarize data of class "bathy"
summary(at1)
```

---

readGEBCO.bathy	<i>Read bathymetric data from a GEBCO file</i>
-----------------	--

---

### Description

Imports 30-sec and 1-min bathymetric data from a .nc file downloaded on the GEBCO website.

### Usage

```
readGEBCO.bathy(file, resolution = 1, sid = FALSE)
```

### Arguments

file	name of the .nc file
resolution	resolution of the grid, in units of the selected database (default is 1; see details)
sid	logical. Is the data file containing SID information?

### Details

readGEBCO.bathy reads a 30 arcseconds or 1 arcminute bathymetry file downloaded from the GEBCO (General Bathymetric Chart of the Oceans) website (British Oceanographic Data Center). The website allows the download of bathymetric data in the netCDF format. readGEBCO.bathy uses the ncdf4 package to load the data into R, and parses it into an object of class bathy.

Data can be downloaded from the 30 arcseconds database (GEBCO\_08) or the 1 arcminute database (GEBCO\_1min, the default). A third database type, GEBCO\_08 SID, is available from the website. This database includes a source identifier specifying which grid cells have depth information based on soundings ; it does not include bathymetry or topography data. readGEBCO.bathy can read this type of database when sid is set to TRUE. Then only the SID information will be included in the object of class bathy. Therefore, to display a map with both the bathymetry and the SID information, you will have to download both datasets from GEBCO, and import and plot both independently.

The argument resolution specifies the resolution of the object of class bathy. Because the resolution of GEBCO data is rather fine, we offer the possibility of downsizing the dataset with resolution. resolution is in units of the selected database: in "GEBCO\_1min", resolution is in minutes; in "GEBCO\_08", resolution is in 30 arcseconds (that is, resolution = 3 corresponds to 3x30sec, or 1.5 arcminute).

### Value

The output of readGEBCO.bathy is a matrix of class bathy, which dimensions depends on the resolution specified (one-minute, the original GEBCO resolution, is the default). The class bathy has its own methods for summarizing and plotting the data.

## End(Not run)
```

---

scaleBathy

*Adds a scale to a map*

---

**Description**

Uses geographic information from object of class `bathy` to calculate and plot a scale in kilometer.

**Usage**

```
scaleBathy(mat, deg=1, x="bottomleft", y=NULL, inset=10, angle=90, ...)
```

**Arguments**

mat	bathymetric data matrix of class bathy, imported using read.bathy
deg	the number of degrees of longitudes to convert into kilometers (default is 1)
x, y	the coordinates used to plot the scale on the map (see Details)
inset	when x is a keyword (e.g. "bottomleft"), inset is a percentage of the plotting space controlling the relative position of the plotted scale (see Examples)
angle	angle from the shaft of the arrow to the edge of the arrow head
...	further arguments to be passed to text

**Details**

scaleBathy is a simple utility to add a scale to the lower left corner of a bathy plot. The distance in kilometers between two points separated by 1 degree longitude is calculated based on the minimum latitude of the bathy object used to plot the map. Option deg allows the user to plot the distance separating more than one degree (default is one).

The plotting coordinates x and y either correspond to two points on the map (i.e. longitude and latitude of the point where the scale should be plotted), or correspond to a keyword (set with x, y being set to NULL) from the list "bottomright", "bottomleft", "topright", "topleft". When a keyword is used, the option inset controls how far the scale will be from the edges of the plot.

**Value**

a scale added to the active graphical device

**Note**

The calculation formula is from function map.scale of package maps. 6372.798 km is used as the Earth radius.

---

space.pies

*Automatic placement of piecharts on maps*

---

## Description

Attempts to automatically place piecharts on maps, avoiding overlap. Work in progress...

## Usage

```

space.pies(x, y, pie.slices, pie.colors=NULL, pie.radius=1, pie.space=5,
           link=TRUE, seg.lwd=1, seg.col=1, seg.lty=1, coord=NULL)

```

## Arguments

x	the longitude of the anchor point for the piechart
y	the latitude of the anchor point for the piechart
pie.slices	a table with the counts to draw pies (col: pie categories, or slices; rows: sites on the map)
pie.colors	a table with the colors to draw pies (col: pie categories, or slices; rows: sites on the map)
pie.radius	size of the piechart
pie.space	factor of spacing between the anchor and the pie (the larger, the farther the pie from the anchor)
link	logical; whether to add a segment to link pie and anchor
seg.lwd	the line width of the link
seg.col	the line color of the link
seg.lty	the line type of the link
coord	when coord = NULL (default), placement is automatic. Otherwise, a 2-col table of lon/lat for pies.

## Details

space.pies tries to position piecharts on a map while avoiding overlap between them. The function heavily relies on two other functions. floating.pie from package plotrix is used to draw individual piecharts. floating.pie treats one pie at a time; space.pies can handle one or multiple pies by looping floating.pie. pointLabels from package maptools was modified to find the best placement for the pies, given their size and distance from their anchor point. pointLabels was originally meant to automatically place text labels, not objects; the modified version contained in space.pies uses the coordinates chosen by pointLabels for text. The algorithm used is simulating annealing (SANN). You can get a different result each time you run space.pies, because pointLabel finds one good solution out of many. If you are not satisfied by the solution, you can try running the function again.

The argument coord allows to choose between the automatic placement outlined above, and a user-defined list of longitudes and latitudes (in a two-column table format) for plotting the piecharts.

Anchor point: spatial location of the data corresponding to the piechart (e.g. a sampling point).

## Value

Piechart(s) added to a plot.

## Author(s)

Eric Pante, using functions plotrix::floating.pie and maptools::pointLabel.

subsetBathy

*Creates bathy objects from larger bathy objects*

---

## Description

Generates rectangular or non rectangular bathy objects by extracting bathymetric data from larger bathy objects.

## Usage

```
subsetBathy(mat, x, y=NULL, locator=TRUE, ...)
```

## Arguments

mat	Bathymetric data matrix of class bathy, as imported with read.bathy.
x	Either a list of two elements (numeric vectors of longitude and latitude), a 2-column matrix or data.frame of longitudes and latitudes, or a numeric vector of longitudes.
y	Either NULL (default) or a numerical vector of latitudes. Ignored if x is not a numeric vector.
locator	Logical. Whether to choose data points interactively with a map or not. If TRUE (default), a bathymetric map must have been plotted and both x and y are both ignored.
...	Further arguments to be passed to locator when the interactive mode is used (locator=TRUE).

## Details

subsetBathy allows the user to generate new bathy objects by extracting data from larger bathy objects. The extraction of bathymetric data can be done interactively by clicking on a bathymetric map, or by providing longitudes and latitudes for the boundaries for the new bathy object. If two data points are provided, a rectangular area is selected. If more than two points are provided, a polygon is defined by linking the points and the bathymetric data is extracted within the polygon only. subsetBathy relies on the `point.in.polygon` function from package `sp` to identify which points of the initial bathy matrix lie within the boundaries of the user-defined polygon.

## Value

A matrix of class `bathy`.

## Author(s)

Benoit Simon-Bouhet

## Examples

```
# load aleutians dataset
data(aleutians)

# create vectors of latitude and longitude to define the boundary of a polygon
lon <- c(188.56, 189.71, 191, 193.18, 196.18, 196.32, 196.32, 194.34, 188.83)
lat <- c(54.33, 55.88, 56.06, 55.85, 55.23, 54.19, 52.01, 50.52, 51.71)

# plot the initial bathy and overlay the polygon
plot(aleutians, image=TRUE, land=TRUE, lwd=.2)
polygon(lon,lat)

# Use of subsetBathy to extract the new bathy object
zoomed <- subsetBathy(aleutians, x=lon, y=lat, locator=FALSE)

# plot the new bathy object
dev.new() ; plot(zoomed, land=TRUE, image=TRUE, lwd=.2)

# alternatively once the map is plotted, use the interactive mode:
## Not run:
```

```

plot(aleutians, image=TRUE, land=TRUE, lwd=.2)
zoomed2 <- subsetBathy(aleutians, pch=19, col=3)
dev.new() ; plot(zoomed2, land=TRUE, image=TRUE, lwd=.2)

## End(Not run)
# click several times and press Escape

```

---

subsetSQL

*Creating and querying local SQL database for bathymetric data*

---

### Description

subsetSQL queries the local SQL database created with setSQL to extract smaller data subsets.

### Usage

```

setSQL(bathy, header = TRUE, sep = ",", db.name = "bathy_db")
subsetSQL(min_lon, max_lon, min_lat, max_lat, db.name = "bathy_db")

```

### Arguments

bathy	A text file containing a comma-separated, three-column table with longitude, latitude and depth data (no default)
header	does the xyz file contains a row of column names (default = TRUE)
sep	character separating columns in the xyz file, (default=",")
min_lon	minimum longitude of the data to be extracted from the local SQL database
max_lon	maximum longitude of the data to be extracted from the local SQL database
min_lat	minimum latitude of the data to be extracted from the local SQL database
max_lat	maximum latitude of the data to be extracted from the local SQL database
db.name	The name of (or path to) the SQL database to be created on disk by setSQL or from which subsetSQL will extract data ("bathy_db" by default)

### Details

Functions setSQL and subsetSQL were built to work together. setSQL builds an SQL database and saves it on disk. subsetSQL queries that local database and the fields min\_lon, max\_lon, etc, are used to extract a subset of the database. The functions were built as two entities so that multiple queries can be done multiple times, without re-building the database each time. These functions were designed to access the very large (>5Go) ETOPO1 file that can be downloaded from the NOAA website (<https://www.ngdc.noaa.gov/mgg/global/global.html>)

### Value

setSQL returns TRUE if the database was successfully created. subsetSQL returns a matrix of class bathy that can directly be used with plot.bathy.

**Note**

If unspecified, db.name is set to "bathy\_db" by default. Thus, there must be no database file called bathy\_db in the working directory prior to running setSQL unless a different name is used for the new database. Make sure that your "bathy" input is a xyz text file (for function setSQL) with 3 columns containing longitude, latitude and depth data, in that order. setSQL and subsetSQL were modified on Nov. 2, 2014 to comply with RSQLite 1.0.0.

**Examples**

```
## Not run:
# load NW Atlantic data
data(nw.atlantic)

# write data to disk as a comma-separated text file
write.table(nw.atlantic, "NW_Atlantic.csv", sep=",", quote=FALSE, row.names=FALSE)

# prepare SQL database
setSQL(bathy="NW_Atlantic.csv")

# uses data from the newly-created SQL database:
subsetSQL(min_lon=-70,max_lon=-50,
          min_lat=35, max_lat=41) -> test

# visualize the results (of class bathy)
summary(test)

# remove temporary database and CSV files
system("rm bathy_db") # remove file, for unix-like systems
system("rm NW_Atlantic.csv") # remove file, for unix-like systems

## End(Not run)
```

---

summary.bathy

*Summary of bathymetric data of class bathy*

---

**Description**

Summary of bathymetric data of class bathy. Provides geographic bounds and resolution (in minutes) of the dataset, statistics on depth data, and a preview of the bathymetric matrix.

**Usage**

```
## S3 method for class 'bathy'  
summary(object, ...)
```

**Arguments**

```
object      object of class bathy  
...        additional arguments affecting the summary produced (see base function summary).
```

**Value**

Information on the geographic bounds of the dataset (minimum and maximum latitude and longitude), resolution of the matrix in minutes, statistics on the depth data (e.g. min, max, median...), and a preview of the data.

---

trans.mat

*Transition matrix*

---

**Description**

Creates a transition object to be used by `lc.dist` to compute least cost distances between locations.

**Usage**

```
trans.mat(bathy, min.depth=0, max.depth=NULL)
```

## Arguments

`bathy` A matrix of class `bathy`.  
`min.depth`, `max.depth` Numeric. The range of depth between which the path will be possible. The default (`min.depth=0` and `max.depth=NULL`) indicates that the transition between cells of the grid is possible between 0 meters depth and the maximum depth of `bathy`. See details

## Details

`trans.mat` creates a transition object usable by `lc.dist` to compute least cost distances between a set of locations. `trans.mat` rely on the function `raster` from package `raster` (Hijmans & van Etten, 2012. <https://CRAN.R-project.org/package=raster>) and on `transition` from package `gdistance` (van Etten, 2011. <https://CRAN.R-project.org/package=gdistance>).

The transition object contains the probability of transition from one cell of a bathymetric grid to adjacent cells and depends on user defined parameters. `trans.mat` is especially useful when least cost distances need to be calculated between several locations at sea. The default values for `min.depth` and `max.depth` ensure that the path computed by `lc.dist` will be the shortest path possible at sea avoiding land masses. The path can be constrained to a given depth range by setting manually `min.depth` and `max.depth`. For instance, it is possible to limit the possible paths to the continental shelf by setting `max.depth=-200`. Inaccuracies of the bathymetric data can occasionally result in paths crossing land masses. Setting `min.depth` to low negative values (e.g. -10 meters) can limit this problem.

`trans.mat` takes also advantage of the function `geoCorrection` from package `gdistance` (van Etten, 2012. <https://CRAN.R-project.org/package=gdistance>) to take into account map distortions over large areas.

## Value

A transition object.

## Warning

Please be aware that the use of `trans.mat` can be time consuming for large bathymetric datasets. The function takes about one minute to compute a transition matrix for the `hawaii` bathymetric data (bathymetric data of class `bathy` with 599 rows and 419 columns, see [hawaii](#)) on a MacBook Pro with a 2.66 GHz Intel Core i7 processor and 4 Go of RAM.
